Chapter 1: Introduction

What is an Operating System?

What is an Operating System?

A program that acts as an intermediary between a user of a computer and the computer hardware.

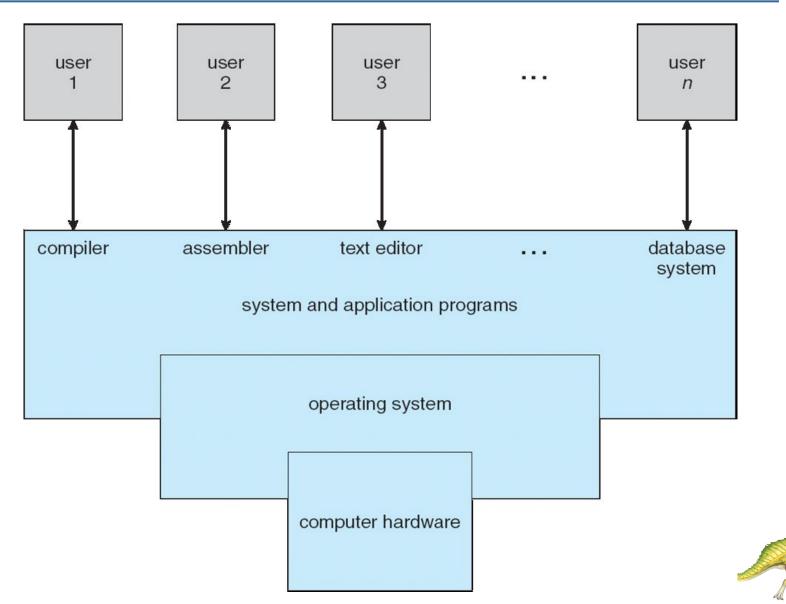

Computer system can be divided into four components:

- Hardware CPU, memory, I/O devices
- Operating system
- Application programs
- Users People, machines, other computers

Four Components of Computer System Structure

Operating System Goals

- Use the computer resources in an efficient manner.
- Make the computer system convenient to use.
- Maximize resource utilization.
- OS is one program that is ALWAYS running on a computer(the kernel).

Operating System's Role-User View

- Ease of use
- Good performance
- Resource Utilization?
- Shared computer such as mainframe or minicomputer must keep all users happy(Accessing the same computer)
- Workstations have dedicated resources but frequently use shared resources from servers
- Handheld computers are resource poor, optimized for usability and battery life
- Some computers have little or no user interface, such as embedded computers in devices and automobiles

Operating System's Role-System View

- OS is a resource allocator
 - Manages all resources
 - Conflict
- OS is a control program
 - Controls execution of programs to prevent errors and improper use of the computer

Operating System Definition (Cont.)

- No universally accepted definition
- "Everything a vendor ships when you order an operating system"
- "The one program running at all times on the computer" is the kernel.

- Difference between Kernel and Operating System.
- System program (Device drivers)
- Application program.

- Mobile Operating Systems often include not only a core kernel but also **Middleware**.
- **Middleware** a set of frameworks that provide additional services to application developers. For eg- Apple's iOS and Google's Android has a core kernel along with middleware that supports databases, multimedia, graphics, etc.

Bootstrap Program

- Typically stored in ROM or EPROM, generally known as firmware
- Initializes all aspects of system
- Loads operating system kernel and starts execution

- Kernel Loaded & Executing □ start System Processes □ Start System Deamons(system Programs that are always running like the kernel)
- In UNIX

init – First System Process \square starts other deamons \square Fully booted System \square system waits for some event to occur \square Interrupt

Computer-System Architecture

- Most systems use a single general-purpose processor
- Multiprocessor systems have more than one CPU.
- All the processors share memory and a clock; communication usually takes place through the shared memory.
- Also known as Tightly-coupled Systems or Parallel Systems.
- Advantages of Parallel Systems:
 - **Increased throughput** When N processors work together, the speed up is huge.
 - Although this speed up ratio is not N times due to sharing of data.
 - **Economical** Multiprocessor save money than multiple single-processor systems coz they share memory and peripherals.
 - Increased reliability If one of the 10 processors fail, other 9 processors should be able to share the work without halting the system.

- **Graceful Degradation** The ability to continue providing the service, even after failure of one processor, is called graceful degradation.
- **Fault Tolerant Systems** Systems designed for graceful degradation are called fault tolerant systems.
- **Job Scheduling** If multiple jobs are ready to be brought into memory, but there is not enough room for all, the system has to choose amongst them. Making this decision is job scheduling.
- **CPU Scheduling** If there are several jobs ready to run at the same time, the system has to choose amongst them. Making this decision is CPU scheduling.

Symmetric Multiprocessor

- Each of the N processors run an identical copy of the OS.
- All systems are peers, there is no master-slave relationship.
- Advantage N processes can be run simultaneously if there are N processors.
- Disadvantage One processor may be sitting idle while the other may be overloaded.

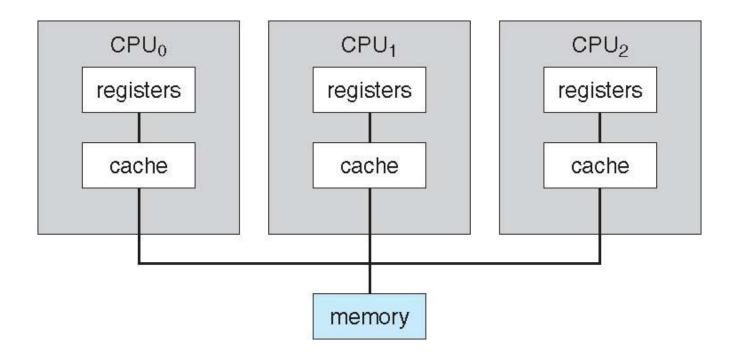

Asymmetric Multiprocessor

- One of the N processor acts as a master and others act act as slaves.
- Master processor assigns a specific task to each of the slave processors.
- Used for large systems.
- Advantage All the slave processors are given the work equally.
- Disadvantage Sharing of memory and other data structures might cause delay sometimes.

Symmetric Multiprocessing Architecture

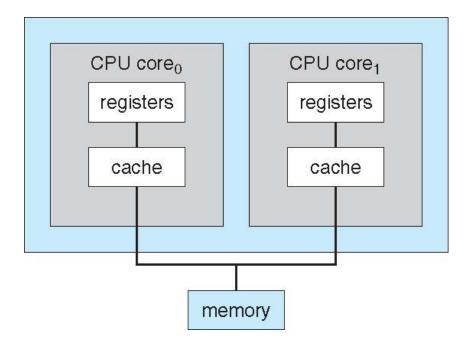

A Dual-Core Design

- Multi-chip and multicore
- Systems containing all chips
 - Chassis containing multiple separate systems

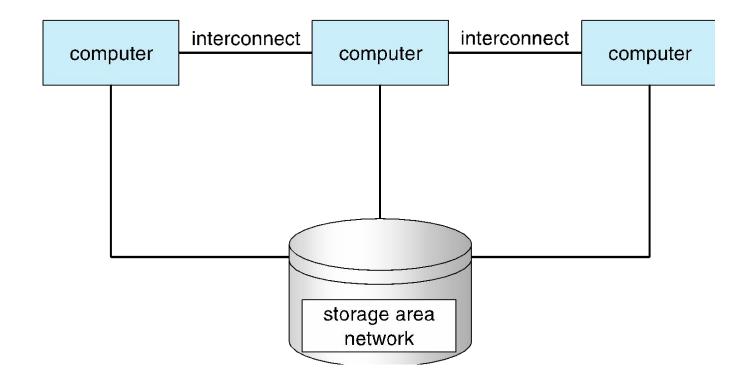

Clustered Systems

- Like multiprocessor systems, but multiple systems working together
 - Usually sharing storage via a **storage-area network (SAN)**
 - Provides a high-availability service which survives failures
 - 4 Asymmetric clustering has one machine in hot-standby mode
 - 4 Symmetric clustering has multiple nodes running applications, monitoring each other
 - Some clusters are for high-performance computing (HPC)
 - 4 Applications must be written to use **parallelization**
 - Some have distributed lock manager (DLM) to avoid conflicting operations

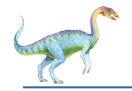

Clustered Systems

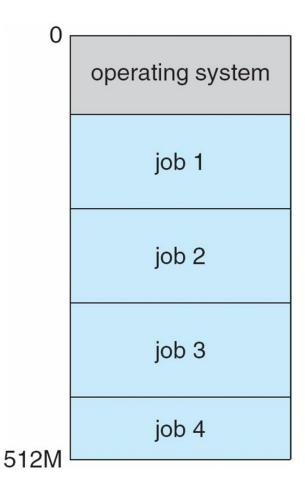

Operating System Structure

- Multiprogramming (Batch system) needed for efficiency
 - Single user cannot keep CPU and I/O devices busy at all times
 - Multiprogramming organizes jobs (code and data) so CPU always has one to execute
 - A subset of total jobs in system is kept in memory
 - One job selected and run via job scheduling
 - When it has to wait (for I/O for example), OS switches to another job
- **Timesharing** (**multitasking**) is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating **interactive** computing
 - Response time should be < 1 second
 - Each user has at least one program executing in memory □ process
 - If several jobs ready to run at the same time \Box **CPU scheduling**
 - If processes don't fit in memory, swapping moves them in and out to run
 - Virtual memory allows execution of processes not completely in memory

Memory Layout for Multiprogrammed System

Operating-System Operations

- **Interrupt driven** (hardware and software)
 - Hardware interrupt by one of the devices
 - Software interrupt (exception or trap):
 - 4 Software error (e.g., division by zero)
 - 4 Request for operating system service
 - 4 Other process problems include infinite loop, processes modifying each other or the operating system

Operating-System Operations (cont.)

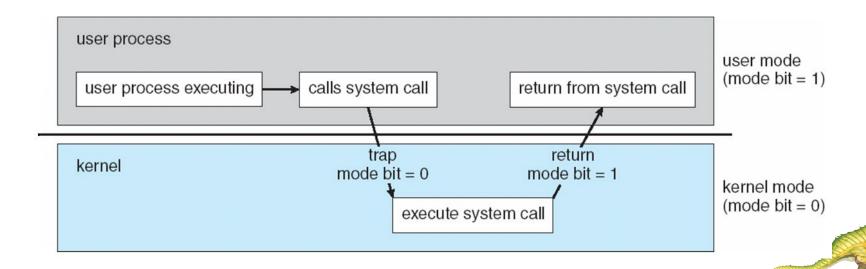

- Dual-mode operation allows OS to protect itself and other system components
 - User mode and kernel mode
 - Mode bit provided by hardware
 - 4 Provides ability to distinguish when system is running user code or kernel code
 - 4 Some instructions designated as **privileged**, only executable in kernel mode
 - 4 System call changes mode to kernel, return from call resets it to user
- Increasingly CPUs support multi-mode operations
 - i.e. virtual machine manager (VMM) mode for guest VMs

Transition from User to Kernel Mode

- Timer to prevent infinite loop / process hogging resources
 - Timer is set to interrupt the computer after some time period
 - Keep a counter that is decremented by the physical clock.
 - Operating system set the counter (privileged instruction)
 - When counter zero generate an interrupt
 - Set up before scheduling process to regain control or terminate program that exceeds allotted time

Distributed Systems

- Distributed Systems are multiple single-processor system connected through a network.
- The computation is distributed among several physical processors connected in a network.
- Each processor has its own local memory.
- Processors communicate with one another through various communications lines, such as high-speed buses or telephone lines.
- Also known as Loosely-coupled Systems.

Networks

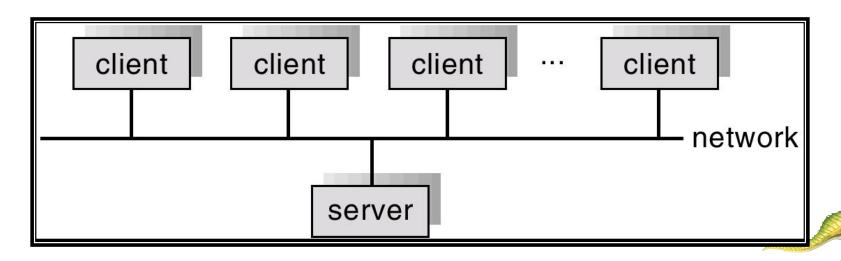

- Local Area Network (LAN) exists in a room, floor or a building.
- Wide Area Network (WAN) exists between buildings, cities, countries.
- Small Area Network exists in a range of several feet. eg-used for Bluetooth device.

Distributed System

- Client-Server System
- Peer-to-Peer System

General Structure of Client-Server

Peer-to-Peer System

- All systems are peers, there is no master-slave relationship.
- All N single processors can run separate tasks.

Clustered Systems

- Clustered Systems are multiple single-processor system connected through a network with shared storage.
- Types of clustered systems:
 - 4 Asymmetric clustering
 - 4 Symmetric clustering

Asymmetric Clustering

- One machine is in standby mode while the other is running the applications.
- If the running machine fails, the standby mode machine becomes active.
- Advantage Very easy to recover from machine failure.
- Disadvantage One machine is ALWAYS in standby mode.

Symmetric Clustering

- All machines run applications and monitor each other too. If any machine fails, its load is shared amongst all others.
- ☐ Advantage No machine is idle.
- ☐ Disadvantage Difficult to share the load.

Real-Time Systems

- Well-defined rigid time constraints are placed on the operation of the processor.
- Used in controlling scientific experiments, medical imaging systems, industrial control system etc.
- Real-Time systems:
 - Hard real-time
 - *Soft* real-time.

Hard Real-Time Systems

- Hard real time systems guarantees that the job will be done on time.
 - All delays in the system are bounded.
 - Secondary storage limited or absent, data stored in read-only memory (ROM).
 - If the time deadline is not met, it may lead to catastrophes.
 - Example Rocket launch.etc

Soft Real-Time Systems

- Failure to meet the time deadline does not lead to catastrophes.
- Soft real-time tasks are given higher priority than.
- Example Industrial control.

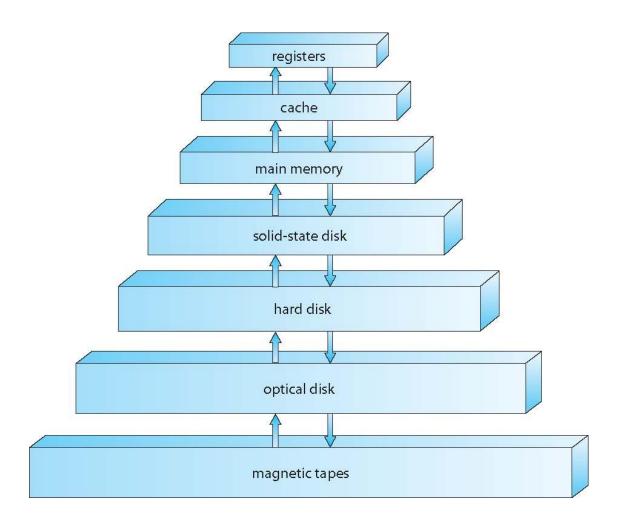

Handheld Systems

- Personal Digital Assistants (PDAs)
- Cellular telephones
- Issues:
 - Limited memory
 - Slow processors
 - Small display screens.

Storage-Device Hierarchy

Caching

- Important principle, performed at many levels in a computer (in hardware, operating system, software)
- Information in use copied from slower to faster storage temporarily
- Faster storage (cache) checked first to determine if information is there
 - If it is, information used directly from the cache (fast)
 - If not, data copied to cache and used there
- Cache smaller than storage being cached
 - Cache management important design problem
 - Cache size and replacement policy

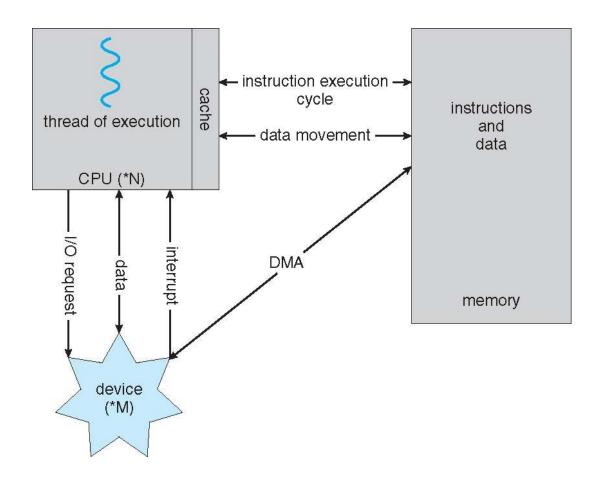

Direct Memory Access Structure

- Used for high-speed I/O devices able to transmit information at close to memory speeds
- Device controller transfers blocks of data from buffer storage directly to main memory without CPU intervention
- Only one interrupt is generated per block, rather than the one interrupt per byte

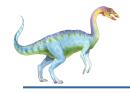

How a Modern Computer Works

A von Neumann architecture

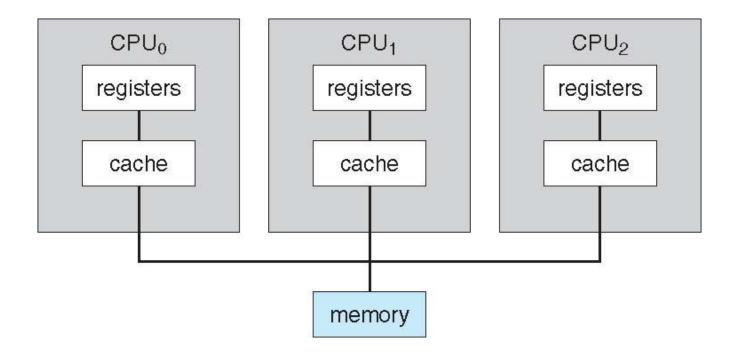

Computer-System Architecture

- Most systems use a single general-purpose processor
 - Most systems have special-purpose processors as well
- Multiprocessors systems growing in use and importance
 - Also known as parallel systems, tightly-coupled systems
 - Advantages include:
 - 1. Increased throughput
 - 2. Economy of scale
 - 3. Increased reliability graceful degradation or fault tolerance
 - Two types:
 - 1. **Asymmetric Multiprocessing** each processor is assigned a specie task.
 - 2. Symmetric Multiprocessing each processor performs all tasks

Symmetric Multiprocessing Architecture

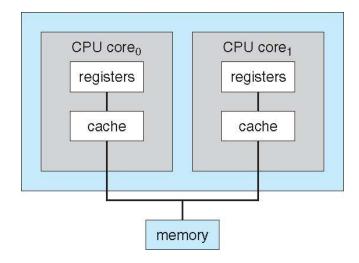

A Dual-Core Design

- Multi-chip and multicore
- Systems containing all chips
 - Chassis containing multiple separate systems

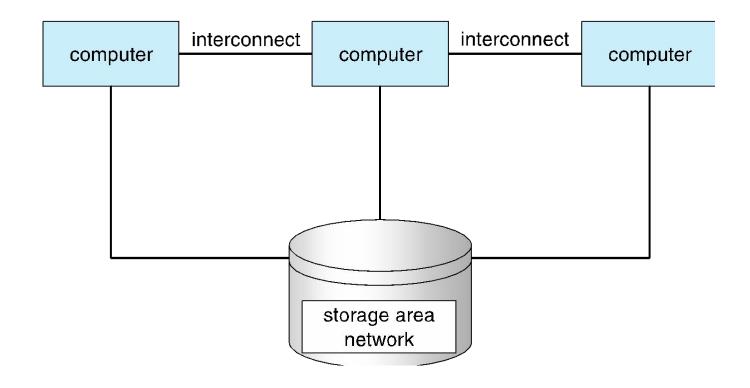

Clustered Systems

- Like multiprocessor systems, but multiple systems working together
 - Usually sharing storage via a storage-area network (SAN)
 - Provides a high-availability service which survives failures
 - 4 Asymmetric clustering has one machine in hot-standby mode
 - 4 Symmetric clustering has multiple nodes running applications, monitoring each other
 - Some clusters are for high-performance computing (HPC)
 - 4 Applications must be written to use **parallelization**
 - Some have distributed lock manager (DLM) to avoid conflicting operations

Clustered Systems

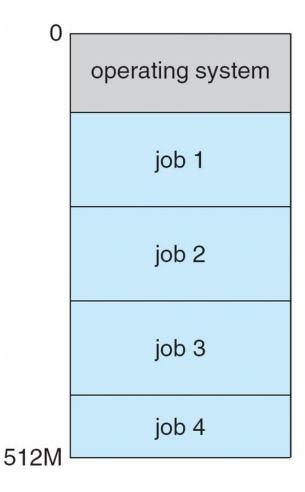

Operating System Structure

- Multiprogramming (Batch system) needed for efficiency
 - Single user cannot keep CPU and I/O devices busy at all times
 - Multiprogramming organizes jobs (code and data) so CPU always has one to execute
 - A subset of total jobs in system is kept in memory
 - One job selected and run via job scheduling
 - When it has to wait (for I/O for example), OS switches to another job
- **Timesharing** (multitasking) is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating interactive computing
 - Response time should be < 1 second
 - Each user has at least one program executing in memory □ process
 - If several jobs ready to run at the same time \Box **CPU scheduling**
 - If processes don't fit in memory, swapping moves them in and out to run
 - Virtual memory allows execution of processes not completely in memory

Memory Layout for Multiprogrammed System

Operating-System Operations

- **Interrupt driven** (hardware and software)
 - Hardware interrupt by one of the devices
 - Software interrupt (exception or trap):
 - 4 Software error (e.g., division by zero)
 - 4 Request for operating system service
 - 4 Other process problems include infinite loop, processes modifying each other or the operating system

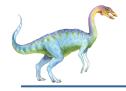

Operating-System Operations (cont.)

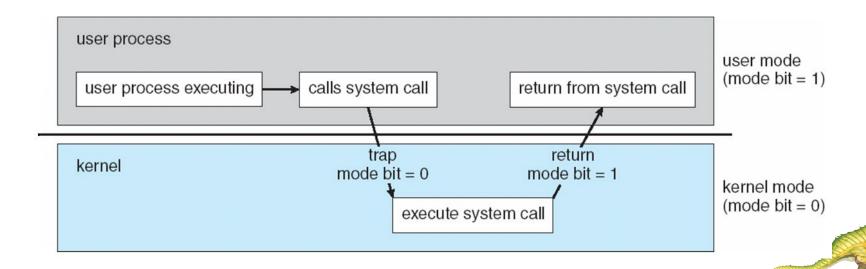

- Dual-mode operation allows OS to protect itself and other system components
 - User mode and kernel mode
 - Mode bit provided by hardware
 - 4 Provides ability to distinguish when system is running user code or kernel code
 - 4 Some instructions designated as **privileged**, only executable in kernel mode
 - 4 System call changes mode to kernel, return from call resets it to user
- Increasingly CPUs support multi-mode operations
 - i.e. virtual machine manager (VMM) mode for guest VMs

Transition from User to Kernel Mode

- Timer to prevent infinite loop / process hogging resources
 - Timer is set to interrupt the computer after some time period
 - Keep a counter that is decremented by the physical clock.
 - Operating system set the counter (privileged instruction)
 - When counter zero generate an interrupt
 - Set up before scheduling process to regain control or terminate program that exceeds allotted time

Process Management

- A process is a program in execution. It is a unit of work within the system. Program is a *passive entity*, process is an *active entity*.
- Process needs resources to accomplish its task
 - CPU, memory, I/O, files
 - Initialization data
- Process termination requires reclaim of any reusable resources
- Single-threaded process has one program counter specifying location of next instruction to execute
 - Process executes instructions sequentially, one at a time, until completion
- Multi-threaded process has one program counter per thread
- Typically system has many processes, some user, some operating system running concurrently on one or more CPUs
 - Concurrency by multiplexing the CPUs among the processes / threads

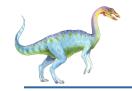

Process Management Activities

The operating system is responsible for the following activities in connection with process management:

- Creating and deleting both user and system processes
- Suspending and resuming processes
- Providing mechanisms for process synchronization
- Providing mechanisms for process communication
- Providing mechanisms for deadlock handling

Memory Management

- To execute a program all (or part) of the instructions must be in memory
- All (or part) of the data that is needed by the program must be in memory.
- Memory management determines what is in memory and when
 - Optimizing CPU utilization and computer response to users
- Memory management activities
 - Keeping track of which parts of memory are currently being used and by whom
 - Deciding which processes (or parts thereof) and data to move into and out of memory
 - Allocating and deallocating memory space as needed

Storage Management

- OS provides uniform, logical view of information storage
 - Abstracts physical properties to logical storage unit file
 - Each medium is controlled by device (i.e., disk drive, tape drive)
 - 4 Varying properties include access speed, capacity, data-transfer rate, access method (sequential or random)
- File-System management
 - Files usually organized into directories
 - Access control on most systems to determine who can access what
 - OS activities include
 - 4 Creating and deleting files and directories
 - 4 Primitives to manipulate files and directories
 - 4 Mapping files onto secondary storage
 - 4 Backup files onto stable (non-volatile) storage media

Mass-Storage Management

- Usually disks used to store data that does not fit in main memory or data that must be kept for a "long" period of time
- Proper management is of central importance
- Entire speed of computer operation hinges on disk subsystem and its algorithms
- OS activities
 - Free-space management
 - Storage allocation
 - Disk scheduling
- Some storage need not be fast
 - Tertiary storage includes optical storage, magnetic tape
 - Still must be managed by OS or applications
 - Varies between WORM (write-once, read-many-times) and RW (read-write)

Performance of Various Levels of Storage

Level	1	2	3	4	5
Name	registers	cache	main memory	solid state disk	magnetic disk
Typical size	< 1 KB	< 16MB	< 64GB	< 1 TB	< 10 TB
Implementation technology	custom memory with multiple ports CMOS	on-chip or off-chip CMOS SRAM	CMOS SRAM	flash memory	magnetic disk
Access time (ns)	0.25 - 0.5	0.5 - 25	80 - 250	25,000 - 50,000	5,000,000
Bandwidth (MB/sec)	20,000 - 100,000	5,000 - 10,000	1,000 - 5,000	500	20 - 150
Managed by	compiler	hardware	operating system	operating system	operating system
Backed by	cache	main memory	disk	disk	disk or tape

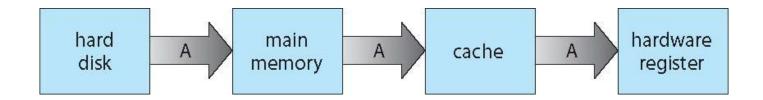

Movement between levels of storage hierarchy can be explicit or implicit

Migration of data "A" from Disk to Register

• Multitasking environments must be careful to use most recent value, no matter where it is stored in the storage hierarchy

- Multiprocessor environment must provide cache coherency in hardware such that all CPUs have the most recent value in their cache
- Distributed environment situation even more complex
 - Several copies of a datum can exist
 - Various solutions covered in Chapter 17

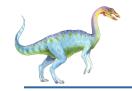

I/O Subsystem

- One purpose of OS is to hide peculiarities of hardware devices from the user
- I/O subsystem responsible for
 - Memory management of I/O including buffering (storing data temporarily while it is being transferred), caching (storing parts of data in faster storage for performance), spooling (the overlapping of output of one job with input of other jobs)
 - General device-driver interface
 - Drivers for specific hardware devices

Protection and Security

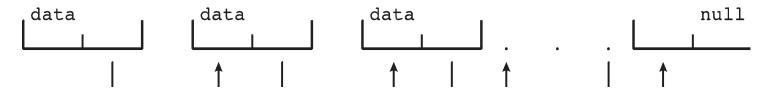

- **Protection** any mechanism for controlling access of processes or users to resources defined by the OS
- Security defense of the system against internal and external attacks
 - Huge range, including denial-of-service, worms, viruses, identity theft, theft of service
- Systems generally first distinguish among users, to determine who can do what
 - User identities (user IDs, security IDs) include name and associated number, one per user
 - User ID then associated with all files, processes of that user to determine access control
 - Group identifier (group ID) allows set of users to be defined and controls managed, then also associated with each process, file
 - Privilege escalation allows user to change to effective ID with more rights

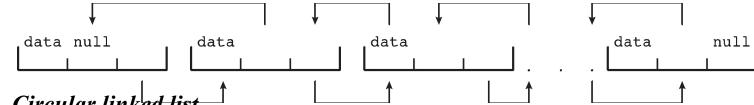

Kernel Data Structures

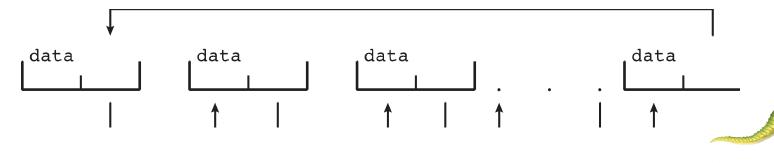

- Many similar to standard programming data structures
- Singly linked list

Doubly linked list

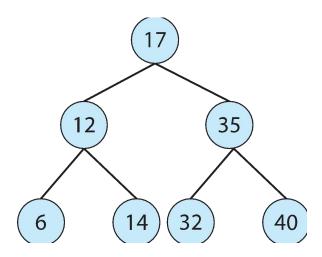

Circular linked list

Kernel Data Structures

- Binary search tree left <= right
 - Search performance is O(n)
 - Balanced binary search tree is O(lg n)

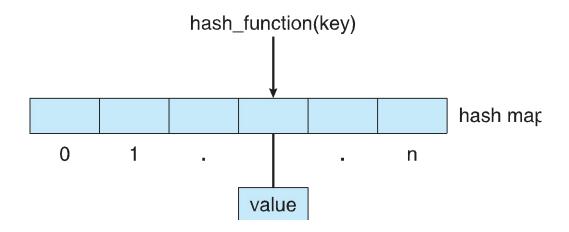

Kernel Data Structures

Hash function can create a hash map

- Bitmap string of n binary digits representing the status of n items
- Linux data structures defined in

```
include files <linux/list.h>, <linux/kfifo.h>,
<linux/rbtree.h>
```

Computing Environments - Traditional

- Stand-alone general purpose machines
- But blurred as most systems interconnect with others (i.e., the Internet)
- **Portals** provide web access to internal systems
- **Network computers (thin clients)** are like Web terminals
- Mobile computers interconnect via wireless networks
- Networking becoming ubiquitous even home systems use firewalls to protect home computers from Internet attacks

Computing Environments - Mobile

- Handheld smartphones, tablets, etc
- What is the functional difference between them and a "traditional" laptop?
- Extra feature more OS features (GPS, gyroscope)
- Allows new types of apps like *augmented reality*
- Use IEEE 802.11 wireless, or cellular data networks for connectivity
- Leaders are Apple iOS and Google Android

Computing Environments – Distributed

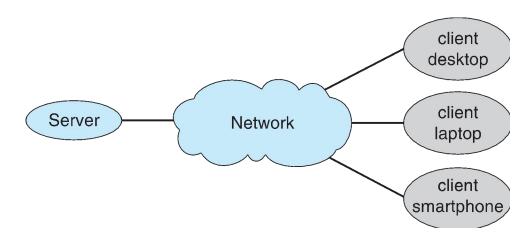

- Distributed computing
 - Collection of separate, possibly heterogeneous, systems networked together
 - 4 Network is a communications path, TCP/IP most common
 - Local Area Network (LAN)
 - Wide Area Network (WAN)
 - Metropolitan Area Network (MAN)
 - Personal Area Network (PAN)
 - Network Operating System provides features between systems across network
 - 4 Communication scheme allows systems to exchange messages
 - 4 Illusion of a single system

Computing Environments – Client-Server

- Client-Server Computing
 - Dumb terminals supplanted by smart PCs
 - Many systems now servers, responding to requests generated by clients
 - 4 Compute-server system provides an interface to client to request services (i.e., database)
 - 4 File-server system provides interface for clients to store and retrieve files

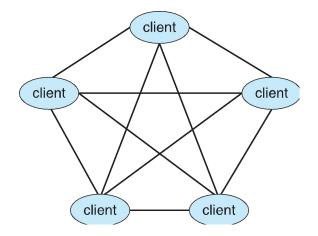

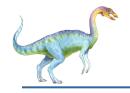

Computing Environments - Peer-to-Peer

- Another model of distributed system
- P2P does not distinguish clients and servers
 - Instead all nodes are considered peers
 - May each act as client, server or both
 - Node must join P2P network
 - 4 Registers its service with central lookup service on network, or
 - 4 Broadcast request for service and respond to requests for service via *discovery protocol*
 - Examples include Napster and Gnutella,
 Voice over IP (VoIP) such as Skype

Computing Environments - Virtualization

- Allows operating systems to run applications within other OSes
 - Vast and growing industry
- Emulation used when source CPU type different from target type (i.e. PowerPC to Intel x86)
 - Generally slowest method
 - When computer language not compiled to native code –
 Interpretation
- Virtualization OS natively compiled for CPU, running guest OSes also natively compiled
 - Consider VMware running WinXP guests, each running applications, all on native WinXP host OS
 - VMM (virtual machine Manager) provides virtualization services

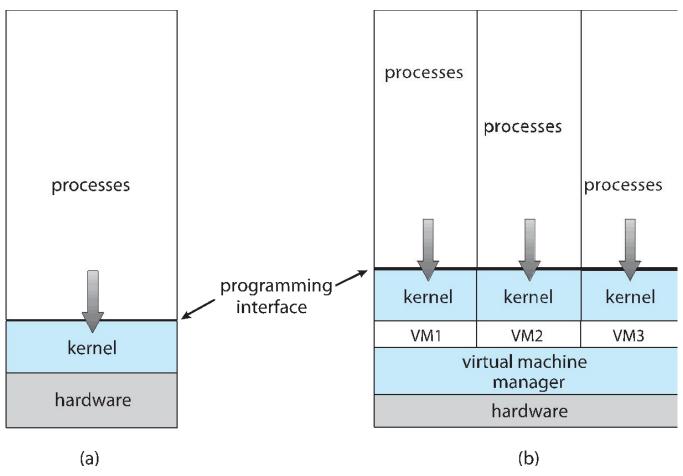

Computing Environments - Virtualization

- Use cases involve laptops and desktops running multiple OSes for exploration or compatibility
 - Apple laptop running Mac OS X host, Windows as a guest
 - Developing apps for multiple OSes without having multiple systems
 - QA testing applications without having multiple systems
 - Executing and managing compute environments within data centers
- VMM can run natively, in which case they are also the host
 - There is no general purpose host then (VMware ESX and Citrix XenServer)

Computing Environments - Virtualization

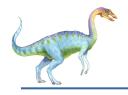

Computing Environments – Cloud Computing

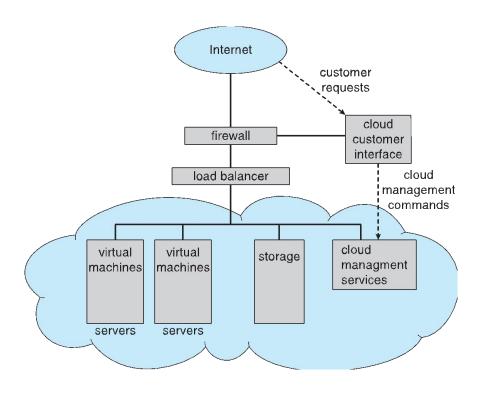

- Delivers computing, storage, even apps as a service across a network
- Logical extension of virtualization because it uses virtualization as the base for it functionality.
 - Amazon EC2 has thousands of servers, millions of virtual machines, petabytes of storage available across the Internet, pay based on usage
- Many types
 - Public cloud available via Internet to anyone willing to pay
 - Private cloud run by a company for the company's own use
 - **Hybrid cloud** includes both public and private cloud components
 - Software as a Service (SaaS) one or more applications available via the Internet (i.e., word processor)
 - Platform as a Service (PaaS) software stack ready for application use via the Internet (i.e., a database server)
 - Infrastructure as a Service (IaaS) servers or storage available over Internet (i.e., storage available for backup use)

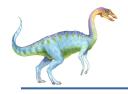

Computing Environments – Cloud Computing

- Cloud computing environments composed of traditional OSes, plus VMMs, plus cloud management tools
 - Internet connectivity requires security like firewalls
 - Load balancers spread traffic across multiple applications

Computing Environments – Real-Time Embedded Systems

- Real-time embedded systems most prevalent form of computers
 - Vary considerable, special purpose, limited purpose OS, real-time
 - Use expanding
- Many other special computing environments as well
 - Some have OSes, some perform tasks without an OS
- Real-time OS has well-defined fixed time constraints
 - Processing *must* be done within constraint
 - Correct operation only if constraints met

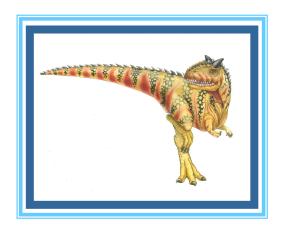

Open-Source Operating Systems

- Operating systems made available in source-code format rather than just binary closed-source
- Counter to the copy protection and Digital Rights Management
 (DRM) movement
- Started by Free Software Foundation (FSF), which has "copyleft"
 GNU Public License (GPL)
- Examples include GNU/Linux and BSD UNIX (including core of Mac OS X), and many more
- Can use VMM like VMware Player (Free on Windows), Virtualbox (open source and free on many platforms http://www.virtualbox.com)
 - Use to run guest operating systems for exploration

End of Chapter 1

- Difference between Symmetric /Asymmetric multiprogramming
- Difference between Symmetric/Asymmetric Clustering
- Difference between Soft Real time/Hard Real Time Systems
